Scheme of low-mass star formation:

M.Hogerheijde 1998, after Shu et al. 1987

Sketch taken from M.Hogerheijde 1998, after the model of Shu et al. 1987

Chemical master equation:

$$\frac{d\langle n_i \rangle}{dt} = \sum_j \left(\nu_{ij} \langle n_j \rangle - \nu_{ji} \langle n_i \rangle \right) + \sum_k \left(\nu_{ik} \langle n_k \rangle - \nu_{ki} \langle n_i \rangle \right)$$

A kind of Boltzmann's equation, describes evolution of any chemically reacting system (living cells, gas-phase reactions in ISM, gas-grain ISM etc.)

Rate equations:

Valid approximation of the Master equation in the limit of infinite number of reacting atoms/molecules

→ Good approximation for gas-phase chemistry

Worse case: grains!

$$N(r) \sim r^{-3.5}, \quad 10^{-6} < r < 10^{-4} \text{ cm}$$

About $\sim 10^6$ binding sites on surface
or even less (small grains)

Abundances of many species per grain
may be ~ 1 or even much less

→ fluctuations of abundances become
important, "mean field" approximation
of rate equations fails in this case

Previous works:

- Tielens & Hagen (1982)
- Charnley (1997, 2001)
- Stantcheva & Herbst (2001 – 2004)
- Group of O.Biham
- Cuppen et al. (2005 – 2008)

Our aims

- To develop a “full-scale” model of chemical evolution of the ISM with proper account for stochastic effects
- To investigate the validity of (modified) rate equations over a set of physical conditions typical for early phases of star formation

Stochastic simulation algorithm – SSA (D. Gillespie, 1976)

- Calculate the sum of all reaction rates at current time moment:

$$r = \sum_{i=1}^M r_i$$

- Select two random numbers r_1 & r_2 uniformly distributed over $[0,1]$

- Choose the time step and the reaction to occur:

$$t = -\frac{\ln(r_1)}{r} \quad \text{and} \quad i = \text{int}\left(\frac{r_2 r}{r_i}\right) + 1$$

- Update abundances:

$$x_i = x_i + \nu_i$$

- If final time is not reached repeat the steps above

Main drawback: in SSA each reaction event is simulated, therefore, may be very slow and computationally demanding

Our Monte Carlo model

- Monte Carlo (Gillespie's SSA): gas-phase coupled with surface chemistry
- 600 species, >6000 reactions
- RATE06 gas-phase ratefile (Woodall++ 07)
- Surface network (Garrod & Herbst 06)
- 0.1 μm uniform olivine grains
- "Low metals" initial abundances (Lee++ 97)
- ISM conditions: $n_{\text{H}} \leq 10^5 \text{ cm}^{-3}$; $T=10-50\text{K}$;
- 1 Myr

Comparison of (modified) rate equations with Monte Carlo approach

- Two models of surface chemistry:
 - T: “fast”, tunneling for H & H₂,
 $E_b/E_D=0.3$ (Hasegawa et al. 1992)
 - H: “slow”, thermal hopping only,
 $E_b/E_D=0.77$ (Katz et al. 1999)
- Methods:
 - Rate Equations
 - Modified RE (Caselli et al. 1998,
Garrod 2008)

Test case:

Agreement map, high surface rates

RE

MRE

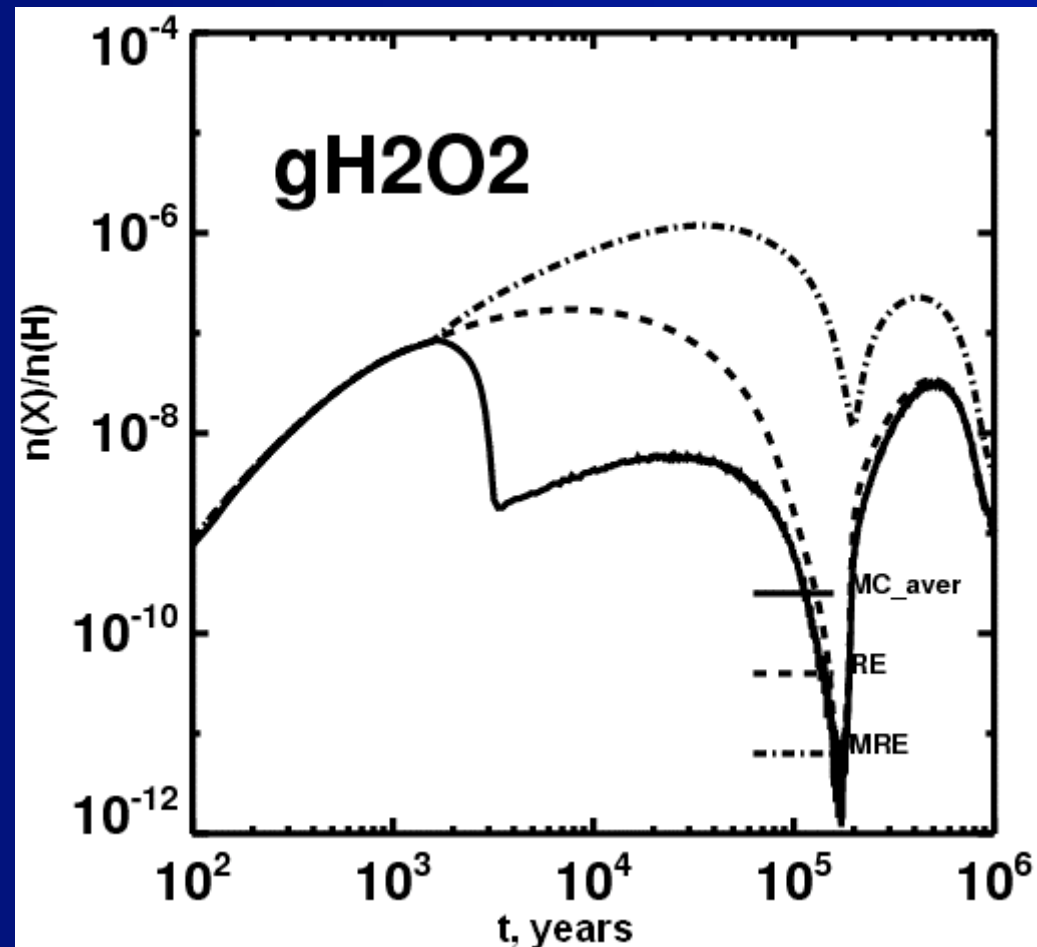

Some processes are missed in (M)RE calculations?

$nH=2*10^4 \text{ cm}^{-3}$

$T=10\text{K}$

Fast surface rates

Warm medium (25–30K): gas-phase abundances are affected!

Agreement map, low surface rates

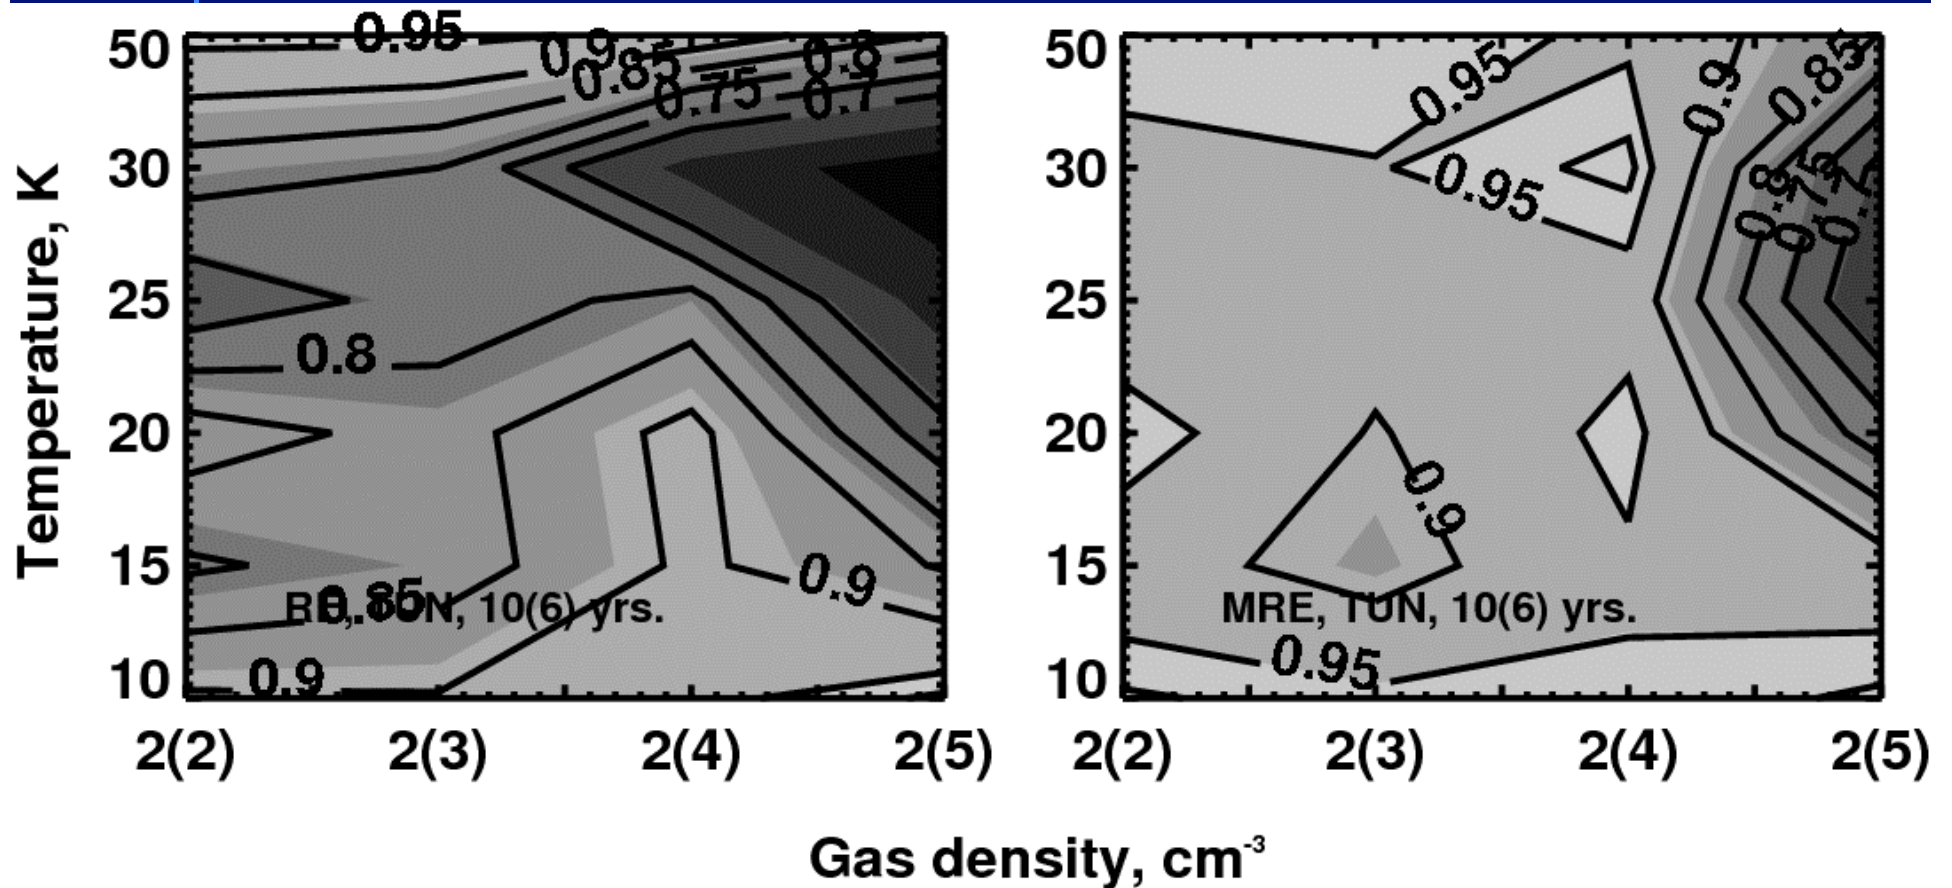

RE

MRE

Disk chemistry:

- Too dense for Monte Carlo to be applicable ($n_{\text{H}} > 10^5 \text{ cm}^{-3}$)
- Approximate methods should be employed to account for stochastic effects

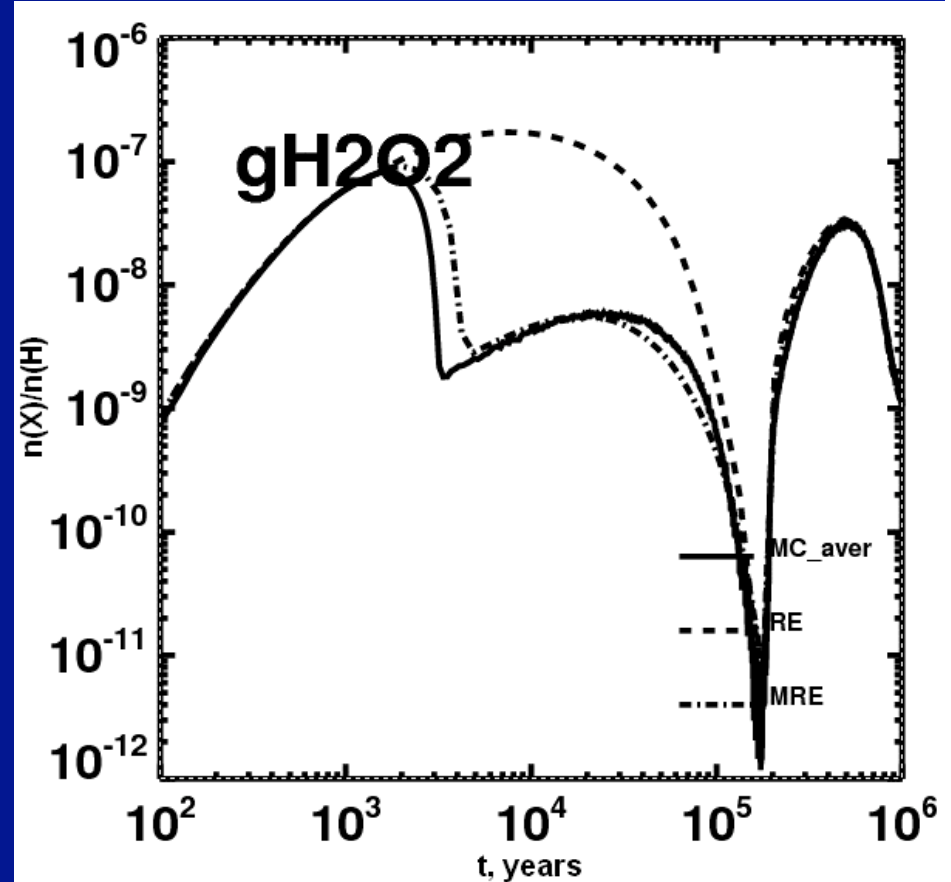

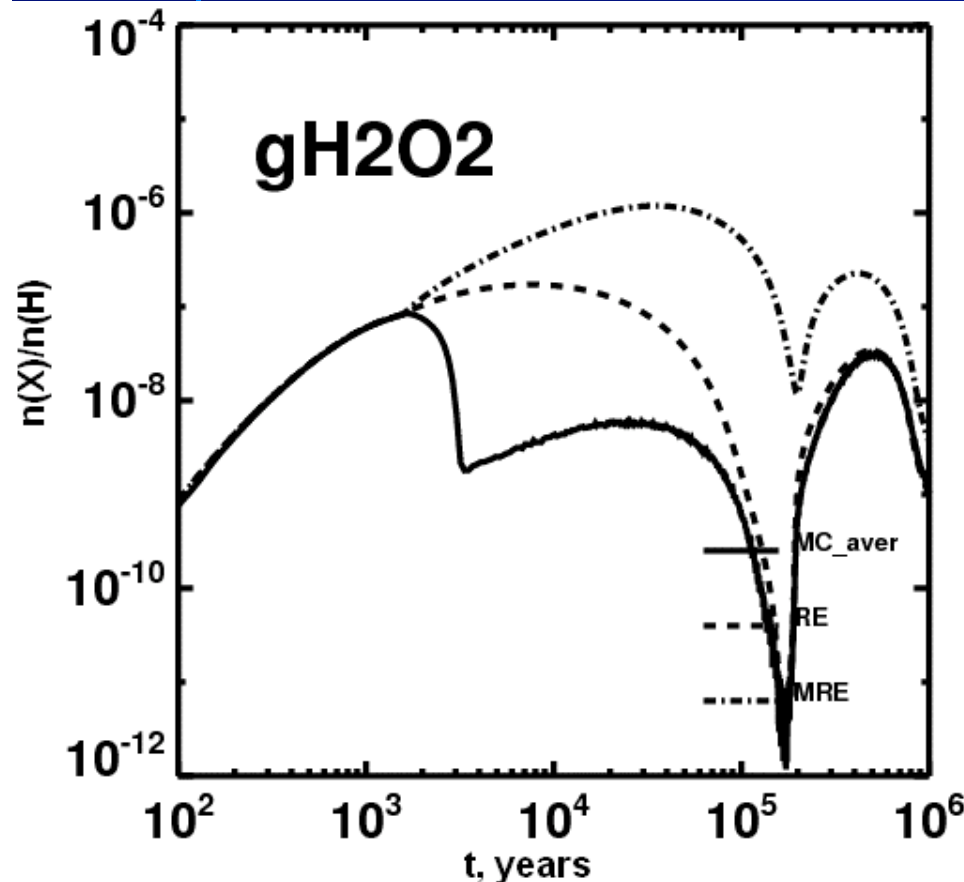

Rob Garrod's new MRE scheme (2008A&A...491...239G):

Rob Garrod's new MRE scheme (2008A&A...491...239G):

Old:

New:

Conclusions

- A Monte Carlo code capable to simulate realistic astrochemical model is developed
- In many cases results of RE and MRE are far from results of MC. Differences are not only quantitative but sometimes qualitative
- Critical temperature range: 25K–30K. Even gas-phase abundances of key species are affected by stochastic effects
- “Hot corino” chemistry can be a “stress test” for this case

Conclusions

- New modified rate approach (Garrod 2008) seems to be the most accurate approximate method at the moment
- Unlike MC it is also suitable for disk chemical modeling!

**Thank you for your
attention!**

$$\bar{X} = \frac{\sum_{i=1}^N X_i \Delta t_i}{\sum_{i=1}^N \Delta t_i}$$
