ISSI Team of Adrian Grocott:

**A statistical investigation into coupled magnetospheric -  
ionospheric dynamics via multi-scale, multi-instrument, data  
assimilation**

$$V_1 = (700, 0) \Rightarrow |V_1| = 700 \text{ m/s}$$

$$V_2 = (400, 300) \Rightarrow |V_2| = 500 \text{ m/s}$$

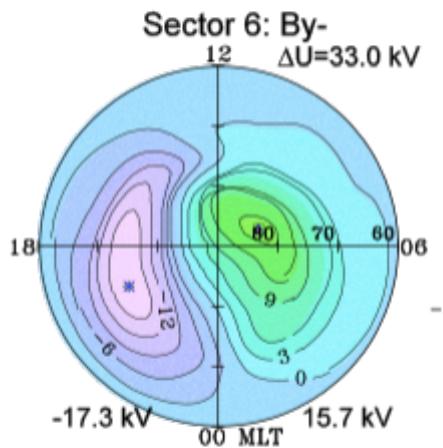

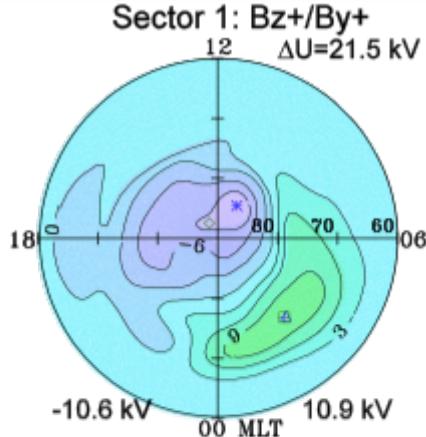

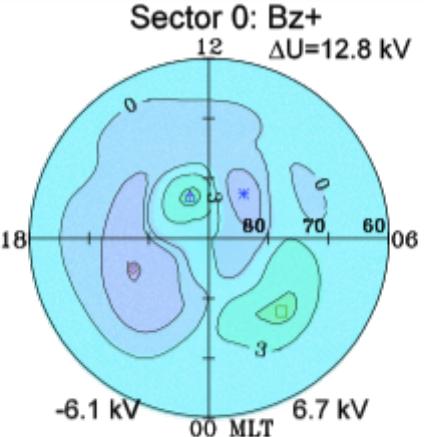

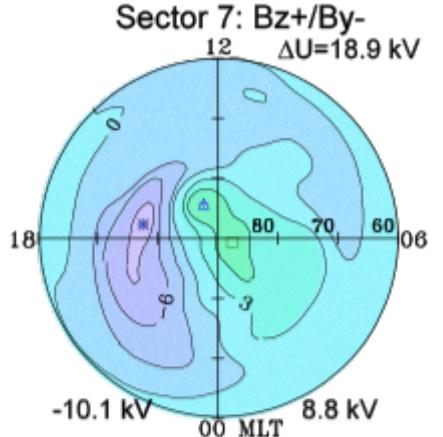

$$V_3 = (-300, 400) \Rightarrow |V_3| = 500 \text{ m/s}$$

$$V_{\text{vector}} = (267, 233) \Rightarrow |V_{\text{vector}}| = 354 \text{ m/s}$$

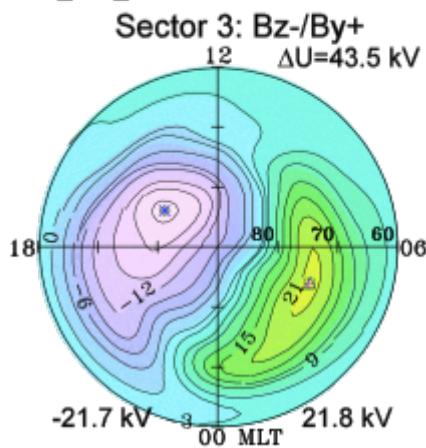

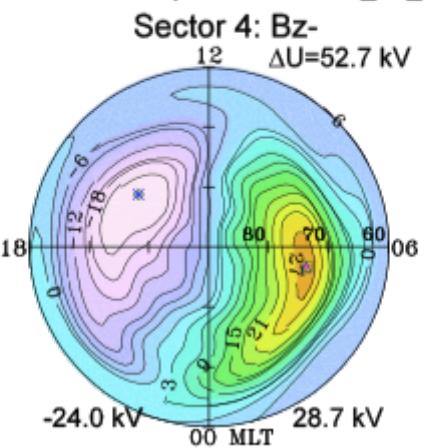

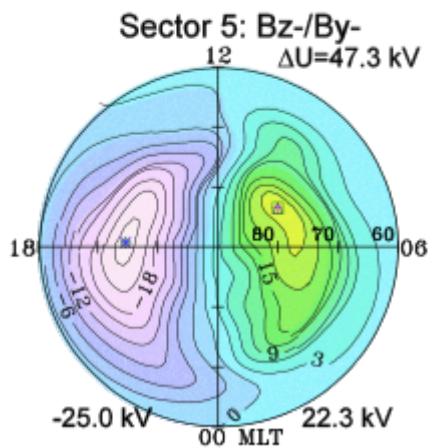

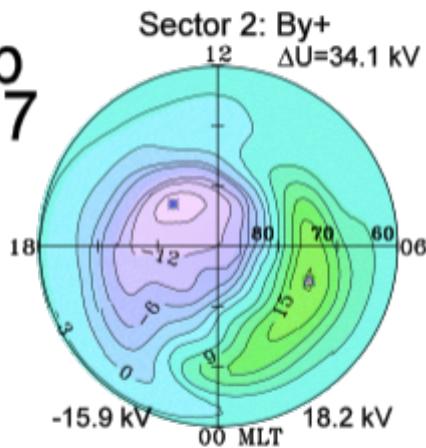

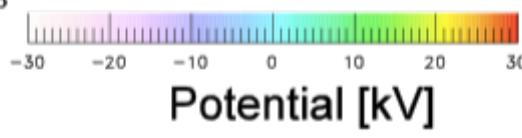

$$V_{\text{scalar}} = (369, 430) \Rightarrow |V_{\text{scalar}}| = 567 \text{ m/s}$$

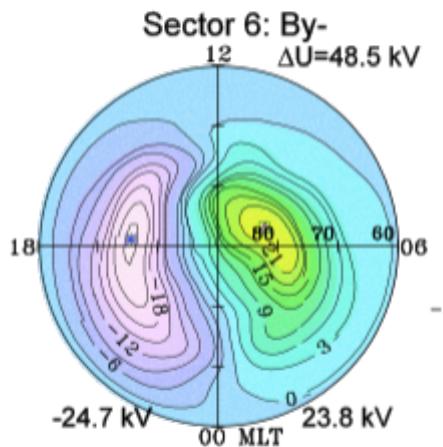

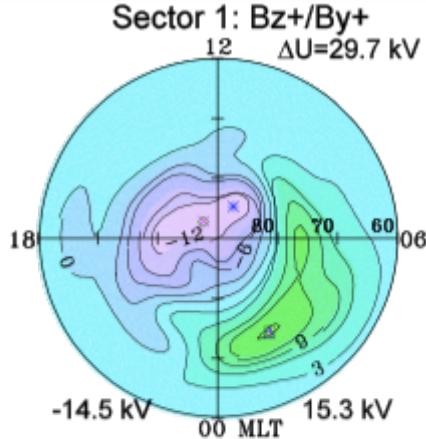

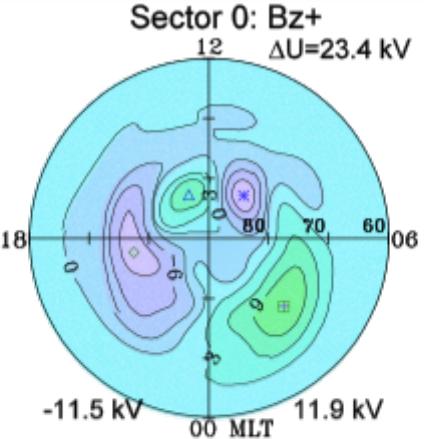

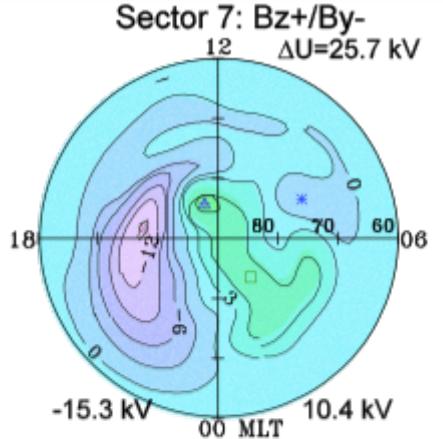

bias value = 0.6146

$\alpha = 8.21 \text{ deg}$

7	$B_z + / B_y -$	18	25	18.9	22.4	25.7	29.5

**Table 1.** Polar cap potential drop between the main cells of the statistical plasma drift patterns obtained from mapped EDI Cluster measurements for 8 separate sectors. The first two data columns are taken from Table 3 in Haaland et al. (2007) (called henceforth “paper I”) and comprise the interval 2001/02–2006/03. They are compared with more recent estimations comprising an extended interval of EDI measurements from 2001/02–2009/07 with both “vector averaging” (Fig. 2 and “scalar averaging” (Fig. 3 of the drift vector magnitudes during the binning process (see also Figure 4). <sup>1</sup> N = northern hemisphere (see Figure 7 in Paper I), S = southern hemisphere (see Figure 8 in Paper I).
